#### Exercise 1: Communication Complexity of Set Disjointness

In the lecture we studied the communication complexity of the equality function. Now we consider the disjointness function: Alice and Bob are given subsets  $X, Y \subseteq \{1, \dots, k\}$  and need to determine whether they are disjoint. Each subset can be represented by a string. E.g. we define the  $i^{\text{th}}$  bit of  $x \in \{0, 1\}^k$  as  $x_i := 1$  if  $i \in X$  and  $x_i := 0$  if  $i \notin X$ . Now define disjointness of  $X$  and  $Y$  as:

$$DISJ(x, y) := \begin{cases} 0 & \text{: there is an index } i \text{ such that } x_i = y_i = 1 \\ 1 & \text{: else} \end{cases}$$

- Write down  $M^{DISJ}$  for the  $DISJ$ -function when  $k = 3$ .
- Use the matrix obtained in a) to provide a fooling set of size 4 for  $DISJ$  in case  $k = 3$ .
- In general, prove that  $CC(DISJ) = \Omega(k)$ .

#### Exercise 2: Distinguishing Diameter 2 from 4

In the lecture we stated that when the bandwidth of an edge is limited to  $O(\log n)$ , the diameter of a graph can be computed in  $O(n)$ . In this problem, we show that we can do faster in case we know that all networks/graphs on which we execute an algorithm have either diameter 2 or diameter 4. We start by partitioning the nodes into sets: Let  $s := s(n)$  be a threshold and define the set of high degree nodes  $H := \{v \in V \mid d(v) \geq s\}$  and the set of low degree nodes  $L := \{v \in V \mid d(v) < s\}$ . Next, we define: An  $H$ -dominating set  $DOM$  is a subset  $DOM \subseteq V$  of the nodes such that each node in  $H$  is either in the set  $DOM$  or adjacent to a node in the set  $DOM$ . Assume in the following, that we can compute an  $H$ -dominating set  $DOM$  of size  $\frac{n \log n}{s}$  in time  $O(D)$ .

---

**Algorithm 1** “2-vs-4”.      Input:  $G$  with diameter 2 or 4      Output: diameter of  $G$

---

```
1: if  $L \neq \emptyset$  then
2:   choose  $v \in L$  ▷ We know: This takes  $O(D)$ .
3:   compute a BFS tree from each vertex in  $N_1(v)$ 
4: else
5:   compute an  $H$ -dominating set  $DOM$  ▷ Use: Assumption
6:   compute a BFS tree from each vertex in  $DOM$ 
7: end if
8: if all BFS trees have depth 2 or 1 then
9:   return 2
10: else
11:   return 4
12: end if
```

---

- a) What is the distributed runtime of Algorithm 2-vs-4? In case you believe that the distributed implementation of a step is not known from the lecture, find a distributed implementation for this step! **Hint: The runtime depends on  $s$  and  $n$ .**
- b) Find a function  $s := s(n)$  such that the runtime is minimized (in terms of  $n$ ).
- c) Prove that if the diameter is 2, then Algorithm 2-vs-4 always returns 2.

Now assume that the diameter of the network is 4 and that we know vertices  $u$  and  $v$  with distance 4 to each other.

- d) Prove that if the algorithm performs a BFS from at least one node  $w \in N_1(u)$  it decides “the diameter is 4”.
- e) In case  $L \neq \emptyset$ : Prove that the algorithm performs a BFS of depth at least 3 from some node  $w$ . **Hint: use d)**
- f) In case  $L = \emptyset$ : Prove that the algorithm performs a BFS of depth at least 3 from some node  $w$ .
- g) Give a high level idea, why you think that this does not violate the lower bound of  $\Omega(n/\log n)$  presented in the lecture!
- h) Assume  $s = \frac{n}{2}$ . Prove or disprove: If the diameter is 2, then Algorithm 2-vs-4 will always compute some BFS tree of depth exactly 2.
