# Knapsack

- $n$  items  $1, \dots, n$ , each item has **weight**  $w_i > 0$  and **value**  $v_i > 0$
- Knapsack (bag) of capacity  $W$
- Goal: pack items into knapsack such that **total weight** is at most  $W$  and **total value is maximized**:

$$\begin{aligned} \max \quad & \sum_{i \in S} v_i \\ \text{s. t.} \quad & S \subseteq \{1, \dots, n\} \text{ and } \sum_{i \in S} w_i \leq W \end{aligned}$$

- E.g.: jobs of length  $w_i$  and value  $v_i$ , server available for  $W$  time units, try to execute a set of jobs that maximizes the total value

# Approximation Algorithm

- The algorithm has a parameter  $\varepsilon > 0$
- We assume that each item alone fits into the knapsack
- We define:

$$V := \max_{1 \leq i \leq n} v_i, \quad \forall i: \hat{v}_i := \left\lceil \frac{v_i n}{\varepsilon V} \right\rceil, \quad \hat{V} := \max_{1 \leq i \leq n} \hat{v}_i$$

- We solve the problem with **integer** values  $\hat{v}_i$  and weights  $w_i$  using dynamic programming in time  $O(n^2 \cdot \hat{V})$
- If solution value  $< V$ , we take item with value  $V$  instead

**Theorem:** The described algorithm runs in time  $O(n^3 / \varepsilon)$ .

**Proof:**

$$\hat{V} = \max_{1 \leq i \leq n} \hat{v}_i = \max_{1 \leq i \leq n} \left\lceil \frac{v_i n}{\varepsilon V} \right\rceil = \left\lceil \frac{V n}{\varepsilon V} \right\rceil = \left\lceil \frac{n}{\varepsilon} \right\rceil$$

# Approximation Algorithm

**Theorem:** The approximation algorithm computes a feasible solution with approximation ratio at most  $1 + \varepsilon$ .

**Proof:**

- Define the set of all feasible solutions (subsets of  $[n]$ )

$$\mathcal{S} := \left\{ S \subseteq \{1, \dots, n\} : \sum_{i \in S} w_i \leq W \right\}$$

- $v(S)$ : value of solution  $S$  w.r.t. values  $v_1, v_2, \dots$   
 $\hat{v}(S)$ : value of solution  $S$  w.r.t. values  $\hat{v}_1, \hat{v}_2, \dots$
- $S^*$ : an optimal solution w.r.t. values  $v_1, v_2, \dots$   
 $\hat{S}$ : an optimal solution w.r.t. values  $\hat{v}_1, \hat{v}_2, \dots$
- Weights are not changed at all, hence,  $\hat{S}$  is a feasible solution

# Approximation Algorithm

**Theorem:** The approximation algorithm computes a feasible solution with approximation ratio at most  $1 + \varepsilon$ .

**Proof:**

- We have

$$v(S^*) = \sum_{i \in S^*} v_i = \max_{S \in \mathcal{S}} \sum_{i \in S} v_i,$$

$$\hat{v}(\hat{S}) = \sum_{i \in \hat{S}} \hat{v}_i = \max_{S \in \mathcal{S}} \sum_{i \in S} \hat{v}_i$$

- Because every item fits into the knapsack, we have

$$\forall i \in \{1, \dots, n\}: v_i \leq V \leq \sum_{j \in S^*} v_j$$

- Also:  $\hat{v}_i = \left\lceil \frac{v_i n}{\varepsilon V} \right\rceil \implies v_i \leq \frac{\varepsilon V}{n} \cdot \hat{v}_i$ , and  $\hat{v}_i \leq \frac{v_i n}{\varepsilon V} + 1$

# Approximation Algorithm

**Theorem:** The approximation algorithm computes a feasible solution with approximation ratio at most  $1 + \varepsilon$ .

**Proof:**

- We have

$$v(S^*) = \sum_{i \in S^*} v_i \leq \frac{\varepsilon V}{n} \cdot \sum_{i \in S^*} \hat{v}_i \leq \frac{\varepsilon V}{n} \cdot \sum_{i \in \hat{S}} \hat{v}_i \leq \frac{\varepsilon V}{n} \cdot \sum_{i \in \hat{S}} \left(1 + \frac{v_i n}{\varepsilon V}\right)$$

- Therefore

$$v(S^*) = \sum_{i \in S^*} v_i \leq \frac{\varepsilon V}{n} \cdot |\hat{S}| + \sum_{i \in \hat{S}} v_i \leq \varepsilon V + v(\hat{S})$$

- If  $v(\hat{S}) \geq V$ :  $v(S^*) \leq (1 + \varepsilon) \cdot v(\hat{S})$
- Otherwise: algorithm solution value is  $V$  and  $v(S^*) \leq (1 + \varepsilon) \cdot V$

# Approximation Schemes

- For every parameter  $\varepsilon > 0$ , the knapsack algorithm computes a  $(1 + \varepsilon)$ -approximation in time  $O(n^3 / \varepsilon)$ .
- For every fixed  $\varepsilon$ , we therefore get a polynomial time approximation algorithm
- An algorithm that computes an  $(1 + \varepsilon)$ -approximation for every  $\varepsilon > 0$  is called an **approximation scheme**.
- If the running time is polynomial for every fixed  $\varepsilon$ , we say that the algorithm is a **polynomial time approximation scheme (PTAS)**
- If the running time is also **polynomial in  $1/\varepsilon$** , the algorithm is a **fully polynomial time approximation scheme (FPTAS)**
- Thus, the described alg. is an FPTAS for the knapsack problem
