# Graphs

Extremely important concept in computer science

**Graph**  $G = (V, E)$

- $V$ : node (or vertex) set
- $E \subseteq V^2$ : edge set
  - Simple graph: no self-loops, no multiple edges
  - Undirected graph: we often think of edges as sets of size 2 (e.g.,  $\{u, v\}$ )
  - Directed graph: edges are sometimes also called arcs  $(u, v)$
  - Weighted graph: (positive) weight on edges (or nodes)
- (simple) path: sequence  $v_0, \dots, v_k$  of nodes such that  $(v_i, v_{i+1}) \in E$  for all  $i \in \{0, \dots, k - 1\}$
- ...

Many real-world problems can be formulated as optimization problems on graphs

# Graph Optimization: Examples

## Minimum spanning tree (MST):

- Compute min. weight spanning tree of a weighted undir. Graph

## Shortest paths:

- Compute (length) of shortest paths (single source, all pairs, ...)

## Traveling salesperson (TSP):

- Compute shortest TSP path/tour in weighted graph

## Vertex coloring:

- Color the nodes such that neighbors get different colors
- Goal: minimize the number of colors

## Maximum matching:

- Matching: set of pair-wise non-adjacent edges
- Goal: maximize the size of the matching

# Network Flow

## Flow Network:

- Directed graph  $G = (V, E)$ ,  $E \subseteq V^2$
- Each (directed) edge  $e$  has a capacity  $c_e \geq 0$ 
  - Amount of flow (traffic) that the edge can carry
- A single **source** node  $s \in V$  and a single **sink** node  $t \in V$

## Flow: (informally)

- Traffic from  $s$  to  $t$  such that each edge carries at most its capacity

## Examples:

- Highway system: edges are highways, flow is the traffic
- Computer network: edges are network links that can carry packets, nodes are switches
- Fluid network: edges are pipes that carry liquid

# Example: Flow Network

# Network Flow: Definition

**Flow:** function  $f: E \rightarrow \mathbb{R}_{\geq 0}$   $f(e) \geq 0$

- $f(e)$  is the amount of flow carried by edge  $e$

## Capacity Constraints:

- For each edge  $e \in E$ ,  $f(e) \leq c_e$

## Flow Conservation:

- For each node  $v \in V \setminus \{s, t\}$ ,

$$\sum_{e \text{ into } v} f(e) = \sum_{e \text{ out of } v} f(e)$$

## Flow Value:

$$\underline{|f|} := \sum_{e \text{ out of } s} f((s, u)) = \sum_{e \text{ into } t} f((v, t))$$

# Notation

We define:

$$\underline{f^{\text{in}}(v)} := \sum_{\substack{e \text{ into } v}} f(e), \quad f^{\text{out}}(v) := \sum_{\substack{e \text{ out of } v}} f(e)$$

For a set  $S \subseteq V$ :

$$f^{\text{in}}(S) := \sum_{\substack{e \text{ into } S}} f(e), \quad f^{\text{out}}(S) := \sum_{\substack{e \text{ out of } S}} f(e)$$

$f^{\text{in}}(S) = f^{\text{out}}(S)$

**Flow conservation:**  $\forall v \in V \setminus \{s, t\}: \underline{f^{\text{in}}(v)} = \underline{f^{\text{out}}(v)}$

**Flow value:**  $|f| = \underline{f^{\text{out}}(s)} = \underline{f^{\text{in}}(t)}$

**For simplicity:** Assume that all capacities are positive integers
