## Algorithms and Datastructures Summer Term 2022 Exercise Sheet 9

Due: Wednesday, July 06th, 4pm

## Exercise 1: Minimum Spanning Trees

 $(10 \ Points)$ 

Let G = (V, E, w) be an undirected, connected, weighted graph with pairwise distinct edge weights.

(a) Show that G has a *unique* minimum spanning tree.

(5 Points)

(b) Show that the minimum spanning tree T' of G is obtained by the following construction:

Start with  $T' = \emptyset$ . For each cut in G, add the lightest cut edge to T'.

(5 Points)

## Exercise 2: Travelling Salesperson Problem

(10 + 5\* Points)

Let  $p_1, \ldots, p_n \in \mathbb{R}^2$  be points in the euclidean plane. Point  $p_i$  represents the position of city i. The distance between cities i and j is defined as the euclidean distance between the points  $p_i$  and  $p_j$ . A tour is a sequence of cities  $(i_1, \ldots, i_n)$  such that each city is visited exactly once (formally, it is a permutation of  $\{1, \ldots, n\}$ ). The task is to find a tour that minimizes the travelled distance. This problem is probably costly to solve. We therefore aim for a tour that is at most twice as long as a minimal tour.

We can model this as a graph problem, using the graph G=(V,E,w) with  $V=\{p_1,\ldots,p_n\}$  and  $w(p_i,p_j):=\|p_i-p_j\|_2$ . Hence, G is undirected and complete and fulfills the triangle inequality, i.e., for any nodes x,y,z we have  $w(\{x,z\}) \leq w(\{x,y\}) + w(\{y,z\})$ . We aim for a tour  $(i_1,\ldots,i_n)$  such that  $w(p_{i_n},p_{i_1}) + \sum_{j=1}^{n-1} w(p_{i_j},p_{i_{j+1}})$  is small.

- (a) Let G be a weighted, undirected, complete graph that fulfills the triangle inequality. Show that the sequence of nodes obtained by a pre-order traversal of a minimum spanning tree (starting at an arbitrary root) is a tour that is at most twice as long as a minimal tour. (5 Bonus Points)
- (b) Implement an algorithm that computes the pre-order ordering of a minimum spanning tree of G. You may use the templates TSP.py and AdjacencyMatrix.py as well as python modules for heap and union-find data structures<sup>2</sup>. Transfer the graph given in cities.txt into an adjacency matrix and run your algorithm on it. Compute the sum of distances of your tour and write it to erfahrungen.txt. (10 Points)

 $<sup>^{1}</sup>$ The Travelling Salesperson Problem is in the class of  $\mathcal{NP}$ -complete problems for which it is assumed that no algorithm with polynomial runtime exists. However, this has not been proven yet.

<sup>&</sup>lt;sup>2</sup>E.g., heapq and networkx.utils.union\_find. In heapq the function heappush corresponds to the insert operation and heappop to the delete-min operation from the lecture. You can also use heappush and heappop on Python-lists (more details here). If you instantiated an object uf of the class UnionFind, the command uf [i] creates a new set  $\{i\}$  if i does not exist in uf yet and else returns the representative of the set containing i (this combines the functions make-set and find from the lecture. More details here).
