

Algorithms and Datastructures

Winter Term 2024

Exercise Sheet 1

Due: Wednesday, November 6th, 12 pm

Exercise 1: Quicksort

(10 Points)

Implement the algorithm *QuickSort* from the lecture with two different options of how to choose the pivot element: "Element at first position", "Element at random position". Use the template `QuickSort.py` that is provided on the website. Write a unit test for both the `quicksort_divide` and the `quicksort_recursive` method. The unit tests should check at least one non-trivial example. If there are critical cases that are easy to check (e.g., an empty input), you should make a unit test for these cases, too.

Exercise 2: Time Measurement

(5 Points)

Measure the runtime of your *QuickSort* implementation for the two variants of choosing the pivot and for two different kinds of inputs. The first kind of inputs are reversed arrays i.e. arrays of the form $[n, n - 1, \dots, 2, 1]$, the second kind are arrays filled with n random integers. Repeat this for input sizes $n \in \{100, 200, \dots, 5000\}$.¹ Plot the runtimes of all 4 variants (pivot, input) into the same chart.² Use your plots to compare the runtimes and write a short evaluation into the file `experience.txt` (c.f., Task 4).

¹A function to generate the arrays and the time measurements is provided in `QuickSort.py`

²The differences in runtimes will be most distinct if they are plotted in a single chart with n on the x -axis and the runtime $T(n)$ on a *linear* and *logarithmic* y -axis.
